Review of Recent Searches for Rare and Forbidden
Dilepton Decays of Charmed Mesons

David A. Sanders

University, MS 38677, USA

(Written on behalf of the E791 Collaboration)

I briefly review the results of recent searches for flavor-changing neutral current and
lepton-flavor and lepton-number violating decays of $D^+$, $D^+_s$, and $D^0$ mesons (and their
antiparticles) into modes containing muons and electrons. The primary focus is the
results from Fermilab charm hadroproduction experiment E791. E791 examined 24 $\pi\ell\ell$
and $K\ell\ell$ decay modes of $D^+$ and $D^+_s$ and $\ell^+\ell^-$ decay modes of $D^0$. Limits presented by
E791 for 22 rare and forbidden dilepton decays of $D$ mesons were more stringent than
those obtained from previous searches,1 or else were the first reported.

Keywords: Charm, Rare, Forbidden, Decay, Dilepton

1. Introduction

Searches for rare and forbidden decays allow investigation of physics beyond the
Standard Model and of phenomena in mass ranges beyond those available to cur-
rent accelerators. One way to search for physics beyond the Standard Model is to
examine decay modes that are forbidden or else are predicted to occur at a negligi-
ble level (rare). Observing such decays would constitute evidence for new physics,
and measuring their branching fractions would provide insight into how to modify
our theoretical understanding, e.g., by introducing new particles or new gauge cou-
plings. These new mediators could include: leptoquarks, horizontal gauge bosons,
or something even more esoteric.

This review focuses on recent results from the Fermilab experiment E791 search
for 24 decay modes of the neutral and charged $D$ mesons (which contain the heavy
charm quark). These decay modes* fall into three categories:

(i) FCNC – flavor-changing neutral current decays ($D^0 \rightarrow \ell^+\ell^-$ and $D^+_{(d,s)} \rightarrow
h^+\ell^+\ell^-$, in which $h$ is either a $\pi$ or $K$);
(ii) LFV – lepton-flavor violating decays ($D^0 \rightarrow \mu^+\mu^-$, $D^+_s \rightarrow h^+\mu^+\mu^-$, and
$D^+_{(d,s)} \rightarrow h^-\mu^+e^+$, in which the leptons belong to different generations);

*Charge-conjugate modes are included implicitly throughout this paper.
(iii) LNV — lepton-number violating decays \( D^{\pm}_{(d,s)} \rightarrow h^- \ell^+ \ell^+ \), in which the leptons belong to the same generation but have the same sign charge).

Decay modes belonging to (i) occur within the Standard Model via higher-order diagrams, but estimated branching fractions\(^3\) are \(10^{-8}\) to \(10^{-6}\). Such small rates are below the sensitivity of current experiments. However, if additional particles such as supersymmetric squarks or charginos exist, they could contribute additional amplitudes that would make these modes observable. Decay modes belonging to (ii) and (iii) do not conserve lepton number and thus are forbidden within the Standard Model. However, lepton number conservation is not required by Lorentz invariance or gauge invariance, and a number of theoretical extensions to the Standard Model predict lepton-number violation.\(^4\) Many experiments have searched for lepton-number violation in \( K \) decays,\(^5\) and for lepton-number violation and flavor-changing neutral currents in \( D^{0} \rightarrow K^{0} \mu^+ \mu^- \) decays. While many experiments have examined charge 1/3 strange and beauty quarks, investigations of \( D \) mesons look for rare and forbidden decays involving charge 2/3 charm quarks. Charge 2/3 quarks may couple differently than charge 1/3 quarks.\(^4\)

2. E791 Analysis

The data were gathered by the the E791 spectrometer,\(^1\) which recorded \(2 \times 10^{10}\) events with a loose transverse energy trigger. These events were produced by a 500 GeV/c \(\pi^-\) beam interacting in a fixed target consisting of five thin, well separated foils. Track and vertex reconstruction was provided by 23 silicon microstrip planes\(^1\) and 45 wire chamber planes plus, two magnets.

Electron identification (ID) was based on transverse shower shape plus matching wire chamber tracks to shower positions and energies in the electromagnetic calorimeter.\(^1\) The electron ID efficiency varied from 62% below 9 GeV to 45% above 20 GeV. The probability to mis-ID a pion as an electron was about 0.8%.

Muon identification was obtained from two planes of scintillation counters. The first plane (5.5 m \(\times\) 3.0 m) of 15 counters measured the horizontal \(x\) axis while the second plane (3.0 m \(\times\) 2.2 m) of 16 counters measured the vertical \(y\) axis. The counters had about 15 interaction lengths of shielding. Candidate muon tracks were required to pass cuts that were set using \( D^+ \rightarrow K^{0} \mu^+ \nu_\mu \) decays from E791's data.\(^1\) Timing from the \(y\) counters improved \(x\) position resolution. Counter efficiencies were measured using muons originating from the primary beam dump, and were found to be \((99 \pm 1)\%\) for the \(y\) counters and \((69 \pm 3)\%\) for the \(x\) counters. The probability for misidentifying a pion as a muon decreased with increasing momentum; from about 6% at 8 GeV/c to \((1.3 \pm 0.1)\%\) above 20 GeV/c.

After reconstruction,\(^1\) events with evidence of well-separated production (primary) and decay (secondary) vertices were selected to separate charm candidates from background. Secondary vertices had to be separated from the primary vertex by greater than \(20 \sigma_v\) for \( D^+ \) decays and greater than \(12 \sigma_v\) for \( D^0 \) and \( D_s^+ \) decays, where \( \sigma_v\) was the calculated resolution of the measured longitudinal separation. In
addition, the secondary vertex had to be separated from the closest material in the
target foils by greater than $5 \sigma_v$, where $\sigma_v$ was the uncertainty in this separation.
The sum of the vector momenta of the tracks from the secondary vertex was required
to pass within 40 $\mu$m of the primary vertex in the plane perpendicular to the beam.
Finally, the net momentum of the charm candidate transverse to the line connecting
the production and decay vertices had to be less than 300, 250, and 200 MeV/c for $D^0$, $D_s^+$, and $D^+$ candidates, respectively. The decay track candidates passed
approximately 10 times closer to the secondary vertex than to the primary vertex.
These selection criteria and, where possible, the kaon identification\(^8\) requirements,
were the same for the search mode and for its normalization signal.

For this study a “blind” analysis technique was used. Before the selection criteria
were finalized, all events having masses within a mass window $\Delta M_S$ around the
mass of $D^+$, $D_s^+$, or $D^0$ were “masked” so that the presence or absence of any
potential signal candidates would not bias the choice of selection criteria. All criteria
were then chosen by studying signal events generated by a Monte Carlo simulation program (see below) and background events, outside the signal windows, from real
data. Events within the signal windows were unmasked only after this optimization.
Background events were chosen from a mass window $\Delta M_B$ above and below the
signal window $\Delta M_S$. The criteria were chosen to maximize the ratio $N_S/\sqrt{N_B}$,
where $N_S$ and $N_B$ are the numbers of signal and background events, respectively.
Asymmetric windows for the decay modes containing electrons were used to allow
for the bremsstrahlung low-energy tail. The signal windows were:

- $1.84 < M(D^+) < 1.90$ GeV/$c^2$ for $D^+ \to h\mu\mu$,
- $1.78 < M(D^+) < 1.90$ GeV/$c^2$ for $D^+ \to hee$ and $h\mu\mu$,
- $1.95 < M(D_s^+) < 1.99$ GeV/$c^2$ for $D_s^+ \to hh\mu$,
- $1.91 < M(D_s^+) < 1.99$ GeV/$c^2$ for $D_s^+ \to hee$ and $h\mu\mu$,
- $1.85 < M(D^0) < 1.90$ GeV/$c^2$ for $D^0 \to \mu\mu$,
- $1.76 < M(D^0) < 1.90$ GeV/$c^2$ for $D^0 \to hee$ and $\mu\mu$.

The sensitivity of the search was normalized to topologically similar Cabibbo-
favored decays. For $D^+$, $24010 \pm 166$ $D^+ \to K^-\pi^+\pi^+$ decays were used; for $D_s^+$,
$782 \pm 30$ $D_s^+ \to \phi\pi^+$ decays were used; and for $D^0$, $25210 \pm 179$ $D^0 \to K^-\pi^+$ decays were used. The normalization modes widths were $10.5$ MeV/$c^2$ for $D^+$, $9.5$ MeV/$c^2$
for $D_s^+$, and $12$ MeV/$c^2$ for $D^0$. The upper limit for each branching fraction $B_X$
was calculated using the following formula: $B_X = (N_X/N_{Norm}) \cdot (\varepsilon_{Norm}/\varepsilon_X) \cdot B_{Norm}$,
where $N_X$ was the 90% CL upper limit on the number of decays for rare or forbidden
decay mode $X$, and $\varepsilon_X$ was that mode’s detection efficiency. $N_{Norm}$ was the fitted
number of normalization mode decays; $\varepsilon_{Norm}$ was the normalization mode detection
efficiency; and $B_{Norm}$ was the normalization mode branching fraction obtained from the
Particle Data Group.\(^1\)

The ratio of detection efficiencies is given by $\varepsilon_{Norm}/\varepsilon_X = N_{XMC}/N_{XMC}$, where
$N_{XMC}$ and $N_{XMC}$ are the fractions of Monte Carlo events that are reconstructed
and pass final cuts, for the normalization and decay modes, respectively. We use
\textsc{Pythia/Jetset}\textsuperscript{19} as the physics generator and model effects of resolution, geometry, magnetic fields, multiple scattering, interactions in detector material, detector efficiencies, and analysis cuts. The efficiencies for the normalization modes varied from about 0.5\% to 2\% and the search modes varied from about 0.1\% to 2\%.

Monte Carlo studies showed that the experiment’s acceptances are nearly uniform across the Dalitz plots, except that the dilepton identification efficiencies typically dropped to near zero at the dilepton mass threshold. While the loss in efficiency varied channel by channel, the efficiency typically reached its full value at masses only a few hundred MeV/$c^2$ above the dilepton mass threshold. A constant weak-decay matrix element was used when calculating the overall detection efficiencies. Two exceptions to the use of the Monte Carlo simulations in determining relative efficiencies were made: those for Čerenkov identification when the number of kaons in the signal and normalization modes were different, and those for the muon identification. These efficiencies were determined from data.

3. E791 Results

The 90\% CL upper limits $N_X$ were calculated using the method of Feldman and Cousins\textsuperscript{20} to account for background, and then corrected for systematic errors by the method of Cousins and Highland.\textsuperscript{21} In these methods, the numbers of signal events are determined by simple counting, not by a fit. All results are listed in Table 1 and shown in Fig. 1. The kinematic criteria and removal of reflections (see below) were different for the $D^+$, $D^+_s$, and $D^0$.

The upper limits were determined by both the number of candidate events and the expected number of background events within the signal region. Background sources that were not removed by the selection criteria discussed earlier included decays in which hadrons (from real, fully-hadronic decay vertices) were misidentified as leptons. In the case where kaons were misidentified as leptons, candidates had effective masses which lie outside the signal windows. Most of these originated from the Cabibbo-favored modes $D^+ \rightarrow K^- \pi^+ \pi^+$, $D^+_s \rightarrow K^- K^+ \pi^+$, and $D^0 \rightarrow K^- \pi^+$ (and charge conjugates). These Cabibbo-favored reflections were explicitly removed prior to the selection-criteria optimization. There remained two sources of background in the data: hadronic decays with pions misidentified as leptons ($N_{\text{HadID}}$) and “combinatorial” background ($N_{\text{Cmb}}$) arising primarily from false vertices and partially reconstructed charm decays. After selection criteria were applied and the signal windows opened, the number of events within the window was $N_{\text{Obs}} = N_{\text{Sig}} + N_{\text{HadID}} + N_{\text{Cmb}}$.

The background $N_{\text{HadID}}$ arose mainly from singly-Cabibbo-suppressed (SCS) modes. These misidentified leptons can come from hadronic showers reaching the muon counter, decays-in-flight, and random overlaps of tracks from otherwise separate decays (“accidental” sources). A limit for $D^+ \rightarrow K^- \ell^+ \ell^+$ modes was not attempted, as they had relatively large feedthrough signals from copious Cabibbo-favored $K^- \pi^+ \pi^+$ decays. Instead, the observed signals in $K^- \ell^+ \ell^+$ channels were
used to measure three dilepton misidentification rates under the assumption that the observed signals arise entirely from lepton misidentification.

Fig. 1. Final event samples for \( D^+ \) (rows 1–3), \( D_s^+ \) (rows 4–7), and \( D^0 \) (row 8) decays. Solid curves represent estimated background; dotted curves represent signal shape of a number of events equal to a 90\% CL upper limit. Dashed vertical lines are \( \Delta M_S \) windows.

The following misidentification rates were obtained: \( r_{\mu\mu} = (7.3 \pm 2.0) \times 10^{-4} \), \( r_{\mu e} = (2.9 \pm 1.3) \times 10^{-4} \), and \( r_{ee} = (3.4 \pm 1.4) \times 10^{-4} \). Using these rates the numbers of misidentified candidates, \( N_\text{MisID}^{\mu\mu} \) (for \( D^+ \) and \( D_s^+ \)) and \( N_\text{MisID}^{\mu e} \) (for \( D^0 \)), in the signal windows were estimated as follows: \( N_\text{MisID}^{\mu\mu} = r_{\mu\mu} \cdot N_\text{SCS}^{\mu\mu} \) and \( N_\text{MisID}^{\mu e} = r_{\mu e} \cdot N_\text{SCS}^{\mu e} \), where \( N_\text{SCS}^{\mu\mu} \) and \( N_\text{SCS}^{\mu e} \) were the numbers of SCS hadronic
decay candidates within the signal windows. For modes in which two possible pion combinations can contribute, e.g., $D^+ \rightarrow \pi^+ \mu^+ \mu^+$, twice the above rate was used.

To estimate the combinatoric background $N_{\text{Cmb}}$ within a signal window $\Delta M_S$, events having masses within an adjacent background mass window $\Delta M_B$ were counted, and this number ($N_{\Delta M_B}$) was scaled by the relative sizes of these windows: $N_{\text{Cmb}} = (\Delta M_S / \Delta M_B) \cdot N_{\Delta M_B}$. To be conservative in calculating the 90% confidence level upper limits, combinatoric backgrounds were taken to be zero when no events are located above the mass windows. In Table 1 the numbers of combinatoric background, misidentification background, and observed events are presented for all 24 modes. Also previously published results are given for comparison.

</table>

The sources of systematic errors in this analysis included: statistical errors from the fit to the normalization sample $N_{\text{Norm}}$; statistical errors on the numbers of Monte Carlo generated events for both $N_{\text{Norm}}^{MC}$ and $N_X^{MC}$; uncertainties in the calculation of misidentification background; and uncertainties in the relative efficiency.
for each mode, including lepton and kaon tagging efficiencies. These tagging ef-

ciency uncertainties included: 1) the muon counter efficiencies from both Monte

Carlo simulation and hardware performance; 2) kaon Čerenkov identification ef-

ficiency due to differences in kinematics and modeling between data and Monte Carlo

simulated events; and 3) the fraction of signal events (based on simulations) that

would remain outside the signal window due to bremsstrahlung tails. The larger

systematic errors for the $D_s^+$ modes, compared to the $D^+$ and $D^0$ modes, are due

to the uncertainty in the branching fraction for the $D_s^+$ normalization mode. The

sums, taken in quadrature, of these systematic errors are listed in Table 1.

4. Summary

As demonstrated elsewhere,\textsuperscript{3} one can estimate what new mass regions these results

can probe. If one, for simplicity, assumes that $g_{X^0,\chi^0} = g_W$ then for FCNC, using:

$$m_{X^0} \approx m_W \cdot \left[ \frac{BR(D^+ \rightarrow \bar{K}^0 \mu^+ \nu)}{BR(D^+ \rightarrow \pi^+ \mu^+ \mu^-)} \right]^{1/4} \cdot (2.2)$$

one estimates that $m_{X^0} > 800 \text{ GeV}/c^2$. Applying a similar technique for LFV, and

now using the formula:

$$m_{X'} \approx m_W \cdot \left[ \frac{BR(D^+ \rightarrow \bar{K}^0 \mu^+ \nu)}{BR(D^+ \rightarrow \pi^+ \mu^+ e^+ e^-)} \right]^{1/4} \cdot (2.2)$$

one estimates that $m_{X'} > 650 \text{ GeV}/c^2$, consistent with theoretical predictions.\textsuperscript{22}

In summary, a “blind” analysis of data from Fermilab experiment E791 was

used to obtain upper limits on the dilepton branching fractions for flavor-changing neutral current, lepton-number violating, and lepton-family violating decays of $D^+$, $D_s^+$, and $D^0$ mesons. No evidence for any of these decays was found. Therefore,

upper limits on the branching fractions at the 90\% confidence level were presented.

These limits represent significant improvements over previously published results.

Eight new $D_s^+$ search modes were reported.

For the future, FOCUS (Fermilab experiment E831)\textsuperscript{23} will shortly be publishing
their results, which should improve on the E791 results. Also, because of interest

expressed\textsuperscript{24} in resonant decays of $D^0$s, Fermilab experiment E791 will shortly be publishing results of a search for $D^0 \rightarrow V\ell^+\ell^-$ decays.

Acknowledgments

I gratefully acknowledge the assistance of Alan Schwartz for the calculations of the

mass regions probed by these rare and forbidden decays. I would also like to express

gratitude to Zoltan Ligeti, for inviting me to give the talk at the Fermilab Joint

Experimental Theoretical Seminar that was the basis for this review. This research

supported under DOE grant DE-FG05-91ER40622.
